# PROCESSES

24/01/2011 Gursharan Singh Tatla professorgstatla@gmail.com

2

## Process

- A process is a set of sequential steps that are required to do a particular task.
- A process is an instance of a program in execution.
- For e.g.: in Windows, if we edit two text files, simultaneously, in notepad, then it means we are implementing two different instances of the same program.
- For an operating system, these two instances are separate processes of the same application.

3

## Process

- A process needs certain resources such as:
  - CPU Time
  - Memory Files
  - I/O Devices
 to accomplish its task.
- These resources are allocated to the process either when it is created or while it is executing.

www.eazynotes.com 24/01/2011

4

## Process States

- A process goes through a series of process states for performing its task.
- As a process executes, it changes state.
- Various events can cause a process to change state.

www.eazynotes.com 24/01/2011

5

## Process States

- The various states of a process are:

```

graph LR
    new((new)) -- admitted --> ready((ready))
    ready -- interrupt --> running((running))
    running -- exit --> terminated((terminated))
    running -- "I/O or event completion" --> waiting((waiting))
    waiting -- "scheduler dispatch" --> ready
    waiting -- "I/O or event wait" --> running
  
```

www.eazynotes.com 24/01/2011

6

## Process States

- **New:**
  - A process that has just been created.
- **Ready:**
  - The process is ready to be executed.
- **Running:**
  - The process whose instructions are being executed is called running process.

www.eazynotes.com 24/01/2011

## Process States

7

- **Waiting:**
  - The process is waiting for some event to occur such as completion of I/O operation.
- **Terminated:**
  - The process has finished its execution.
- **Note:** Only one process can be *running* on any processor at any instant. However, there can be many processes in *ready* and *waiting* states.

## Process Control Block (PCB)

8

- Process Control Block (PCB) is a data structure used by operating system to store all the information about a process.
- It is also known as Process Descriptor.
- When a process is created, the operating system creates a corresponding PCB.

www.eazynotes.com 24/01/2011

## Process Control Block (PCB)

9

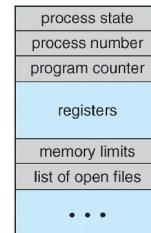

- Information in a PCB is updated during the transition of process states.
- When a process terminates, its PCB is released.
- Each process has a single PCB.

www.eazynotes.com 24/01/2011

## Process Control Block (PCB)

10

- The PCB of a process contains the following information:

www.eazynotes.com 24/01/2011

## Process Control Block (PCB)

11

- **Process Number:** Each process is allocated a unique number for the purpose of identification.
- **Process State:** It specifies the current state of a process.
- **Program Counter:** It indicates the address of next instruction to be executed.

www.eazynotes.com 24/01/2011

## Process Control Block (PCB)

12

- **Registers:** These hold the data or result of calculations. The content of these registers is saved so that a process can be resumed correctly later on.
- **Memory Limits:** It stores the amount of memory units allocated to a process.
- **List of Open Files:** It stores the list of open files and their access rights.

## Process Scheduling

13

- In multiprogramming, several processes are kept in main memory so that when one process is busy in I/O operation, other processes are available to CPU.
- In this way, CPU is busy in executing processes at all times.
- This method of selecting a process to be allocated to CPU is called Process Scheduling.

www.eazynotes.com 24/01/2011

## Process Scheduling

14

- Process scheduling consists of the following sub-functions:
- **Scheduling:** Selecting the process to be executed next on CPU is called scheduling.
  - In this function a process is taken out from a pool of ready processes and is assigned to CPU.
  - This task is done by a component of operating system called **Scheduler**.

www.eazynotes.com 24/01/2011

## Process Scheduling

15

- **Dispatching:** Setting up the execution of the selected process on the CPU is called dispatching.
  - It is done by a component of operating system called **Dispatcher**.
  - Thus, a dispatcher is a program responsible for assigning the CPU to the process, that has been selected by the Scheduler.
- **Context Save:** Saving the status of a running process when its execution is to be suspended is known as context save.

## Scheduling Queues

16

- In multiprogramming, several processes are there in ready or waiting state.
- These processes form a queue.
- The various queues maintained by operating system are:
  - Job Queue
  - Ready Queue
  - Device Queue

www.eazynotes.com 24/01/2011

## Scheduling Queues

17

- **Job Queue:**
  - As the process enter the system, it is put into a job queue. This queue consists of all processes in the system.
- **Ready Queue:**
  - It is a doubly linked list of processes that are residing in the main memory and are ready to run.

www.eazynotes.com 24/01/2011

## Scheduling Queues

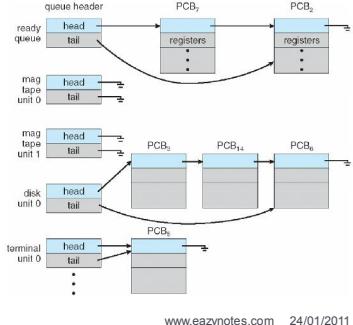

18

- **Device Queue:**
  - It contains all those processes that are waiting for a particular I/O device.
  - Each device has its own device queue.
- Diagram on the next slide shows the queues.

## Context Switch

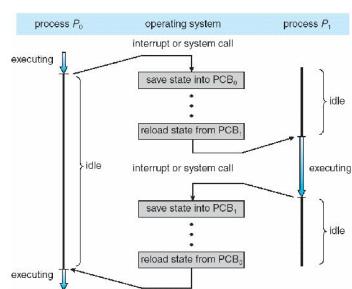

20

- Switching the CPU from one process to another process requires saving the state of old process and loading the saved state of new process.
- This task is known as **Context Switch**.
- When context switch occurs, operating system saves the context of old process in its PCB and loads the saved context of the new process.
